Nperseg = 128,256,512,1024,2048,8k,32k,131k (car à $f_s=4\text{MHz}$, le nombre max d'éch d'une impulsion de 1ms est de 4000 échantillons)

Durée IQ : 32s

Temps de traitement sans la caractérisation : 15 min

Optimisations possibles (non exhaustive):

- Batch inférence
- Quantification
- V100 → H100
- Multi-GPU

BT1.0.2

Paramètres :

nperseg = [128, 256, 512]

noverlap = nperseg / 2

nfft = 512

fc_rec = 2.5 GHz

fs_rec = [4, 20, 100, 500, 1e3, 4e3] MS/s

dt_rec = 513 * nperseg / (2*fs_rec)

sigma_noise = 1mV

sig_types = [['radar'], ['radar', 'cellular']]

Stand by

YOLOv9

<https://arxiv.org/pdf/2402.13616.pdf>

Résout le problème de la perte d'information dans les réseaux profonds en proposant le programmable gradient information (PGI) et le generalized ELAN (GELAN). Cela a permis d'obtenir un nouvel état de l'art des perfs sur MSCOCO.

Des branches sont ajoutées durant l'apprentissage uniquement ne pénalisant pas le temps d'inférence.

RT DETR

Overview

Real-Time Detection Transformer (RT-DETR), developed by Baidu, is a cutting-edge end-to-end object detector that provides real-time performance while maintaining high accuracy. It leverages the power of Vision Transformers (ViT) to efficiently process multiscale features by decoupling intra-scale interaction and cross-scale fusion. RT-DETR is highly adaptable, supporting flexible adjustment of inference speed using different decoder layers without retraining. The model excels on accelerated backends like CUDA with TensorRT, outperforming many other real-time object detectors.

Modèle intéressant pour faire du temps-réel **mais n'a pas (pour le moment) d'implémentation OBB**

Est beaucoup moins considéré car il nécessite un gros préapprentissage or ce n'est pas un frein pour notre cas d'usage.
